Image sequence software You can use software that creates slide shows, in which several photos appear to move across the screen in sequential order. These programs are similar to slide projects in books and often have a control panel where you can adjust the slides' speed, panning from left to right and the like. You can create, edit, and insert images in a sequence that plays back in real time. This type of software uses a series of still images rather than video frames, making the sequence more realistic. Programs like Adobe After Effects and Adobe Premiere Elements are two such programs. The same type of software can provide animation as well. You can create your own animation by using your computer to load images in a sequence and play them back to the viewer in a loop. After Effects is a popular application that provides this type of capability.

This invention relates to a DNA sequence comprising a promoter sequence operably associated with a sequence encoding a biologically active polypeptide, and a method of recombination of the sequences. When a genetic trait is to be introduced into a polypeptide, it is often more preferable to introduce the genetic information directly to the polypeptide itself rather than through a DNA sequence which encodes it. However, it is not always possible to introduce genetic information directly to a polypeptide since many polypeptides are composed of amino acids which do not provide an efficient pathway for the entry of genes or DNA into their structure. Recombinant DNA techniques have made it possible to introduce genetic information directly into a polypeptide. Usually, these techniques employ a vector derived from a virus which has been transformed into a cell containing the gene of interest, as described by Cohen et al. (1971, Proc. Natl. Acad. Sci., USA, 68:2112-2117). In such a case, the viral genome is present in the cell in two copies per cell, whereas the gene of interest is present in the cell as one copy per cell. This system has significant limitations; the number of copies of the gene in the transformed cell is generally limited, and the use of any one gene in the vector is limited to the number of genes per infectious particle. There have been recent attempts to limit the number of genes in a single viral vector. For example, Gillis et al. (1991, Proc. Natl. Acad. Sci., USA, 88:5547-5551) describe a bacterial virus (T3) pseudotyped with influenza virus. In this system, the viral envelope is modified by insertion of foreign genes into sequences encoding viral structural protein segments. A method for inserting foreign genes into a bacterial virus was described by Gillis et al. (1991, Proc. Natl. Acad. Sci., USA, 88:5547-5551). This method uses the helper functions of the viral capsid. The method works well with the T7, T3, and T4 bacteriophages, but tends to be inefficient for larger, non-T-specific bacteriophages such as baculoviruses and herpesviruses. Methods for inserting foreign genes into herpesviruses are described by Huang et al. (1992, J. Virol., 66:1126-1132). The method uses a T cell line infected with a
