The self-assembly of nanotubes and hollow spheres from CdSe quantum dots (QDs) confined in cross-linked alginate is described. The cross-linking density of alginate changes from 0 to 50%. These alginate gels are prepared by Ca²⁺-alginate gelation under controlled acid conditions. The CdSe QDs are encapsulated in the cross-linked alginate gels under acidic conditions. The cross-linking density determines the number of CdSe QDs inside the alginate gels. The QDs, alginate gels and alginate-QD systems were characterized by powder X-ray diffraction, Fourier transform infrared and Raman spectroscopy, X-ray photoelectron spectroscopy and atomic force microscopy. The results show that the cross-linked alginate gels are homogeneous and smooth. The diameter of tubes increases with decreasing the cross-linking density of the alginate gel. The diameter of tubes is
