One typical application for gain reflectors is in the field of communication systems. For example, it is known to use gain reflectors as power couplers in multiple input, single output communication systems in order to provide balanced signals from a plurality of inputs to one or more outputs. As such, each of the inputs may be easily connected to the output without worrying about the outputs being skewed or unbalanced with respect to the others. As another example, it is known to use gain reflectors in optical receivers to convert incident radiation into a local oscillator signal that is phase coherent with the incident radiation. In such an application, a reference signal, such as an in-phase, I.sub.B,
